

An Introduction to WSDM

Committee Draft, February 24, 2006

Document identifier:

wsdm-1.0-intro-primer-cd-01

Location:

<http://docs.oasis-open.org/wsdm/wsdm-1.0-intro-primer-cd-01.pdf>

Editors:

Vaughn Bullard, AmberPoint, Inc. <vbullard@amberpoint.com>

Bryan Murray, Hewlett-Packard <bryan.murray@hp.com>

Kirk Wilson, Computer Associates International <kirk.wilson@ca.com>

Abstract:

This Introduction provides an overview to the WSDM specification and its associated sub-specifications. The introduction is directed towards a wide audience of architects, developers, systems and software integration specialists and users.

In addition, this introduction covers the historical motivations for the creation of WSDM as well as the motivations for why would want to use WSDM as a management specification within their information technology environment.

The introduction provides simple examples of how WSDM can be used in end devices to give the reader ideas of how the WSDM standard can be used in the real world.

This introduction does not provide a definitive source of the WSDM specification. Rather it is intended to provide an easily read and understood summary of the fundamentals of creating and using WSDM-compliant management applications and manageable resources.

Status:

This document is updated periodically on no particular schedule. Send comments to the editor.

Committee members should send comments on this specification to the wsdm@lists.oasis-open.org list. Others should subscribe to and send comments to the wsdm-comment@lists.oasis-open.org list. To subscribe, send an email message to wsdm-comment-request@lists.oasis-open.org with the word "subscribe" as the body of the message.

For information on whether any patents have been disclosed that may be essential to implementing this specification, and any offers of patent licensing terms, please refer to

36 the Intellectual Property Rights section of the WSDM TC web page ([http://www.oasis-](http://www.oasis-open.org/committees/wsdm/)
37 [open.org/committees/wsdm/](http://www.oasis-open.org/committees/wsdm/)).

74

1 Overview

75 The WSDM, or *Web Services Distributed Management*, standard is more than a management
76 protocol, SNMP trap handler, or simple distributed management technology. As a standard, it
77 seeks to unify management infrastructures by providing a vendor, platform, network, and protocol
78 neutral framework for enabling management technologies to access and receive notifications of
79 management-enabled resources. Though built upon a standardized suite of XML [XML]
80 specifications, it provides features to enable resources that other proprietary management
81 technologies do not. It can be used to standardize management for many devices, from network
82 management devices as well as consumer electronic devices, such as televisions, digital video
83 disc players, and PDAs.

84 In this introduction, a detailed explanation will be provided of WSDM without providing the 'how' a
85 manufacturer or developer would do the implementation. The explanation goes into the detail of
86 the historical motivation as well as examples usage of WSDM. In section 2.2 , "A Day in the Life
87 of a Web-Enabled Resource" provides real world scenarios of how organizations could possibly
88 implement WSDM as a management framework.

89 In addition, "The Objectives of WSDM" in section 3, provides a suite of goals the WSDM Standard
90 Technical Committee has set out to achieve. In section 4, "What is WSDM?" a more thorough
91 explanation of the attributes, elements and resources needed are discussed in further detail. In
92 section 5, "The Structure of the WSDM Standard"; the standards management aspect as well as
93 the stack, or suite of technologies, that make up the foundation of WSDM are discussed in detail.
94 Finally, a brief summary is provided as well as an appendix and reference section to links of the
95 base specifications.

96 2 WSDM Explained

97 2.1 Motivation for using WSDM

98 In current Information Technology (IT) environments, there exists a complex collection of
99 heterogeneous systems management technologies and solutions. These heterogeneous IT
100 resources rely upon an ever increasing variety of heterogeneous management technologies. To
101 manage business systems in a more cost effective manner requires the IT operations manager to
102 deal effectively with the complex task of integrating multiple and varied management technologies
103 into a cohesive whole. While providers of management software offer enterprise management
104 solutions that reduce some of this complexity, the offered solutions only provide users with a
105 single point of control. Sometimes, this single point of control exists only within the scope of a
106 specific management domain for a set of tasks or processes. Moreover, it is often difficult to
107 achieve an acceptable level of integration among different enterprise management systems that
108 provides an overall view of cross-application and end-to-end business processes.

109 Currently, the IT industry and users embrace a variety of standards to integrate management
110 products from multiple vendors. From this situation emerges the need for a standard enabling the
111 integration and accommodation of the full variety of means for managing IT resources. The goal
112 of the WSDM standard is to address this expressed need.

113 Web services technology was designed to address the general problem of the integration of
114 applications, especially the integration of applications built with a heterogeneous set of
115 implementation technologies and platforms. The mainstream adoption of open, Web services
116 standards created an opportunity for the systems management community to leverage these
117 technologies for the integration of management applications used to manage heterogeneous IT
118 resources. One may choose to apply the same Web services approach used for integrating
119 applications to the problem of integrating management applications and the management of IT
120 resources. By applying the Web services approach, the systems management infrastructure is
121 positioned as a vendor-neutral, platform-independent foundation allowing the use of a common
122 messaging protocol between a manageable resource and a manageability consumer and among
123 manageability consumers themselves. The WSDM standards specify a common messaging
124 protocol for managed resources and their consumers.

125 The benefits of the WSDM standard are achieved by making the integration of management
126 aspects of diverse IT resources easier and more flexible, and by the coordination of management
127 applications with enterprise business systems. For example, performance metrics of a service are
128 used by a business process when deciding which instance of a Web service to use. By evolving
129 the current management infrastructure to a Web-based standard, the specification enables the
130 migration of existing management processes towards agile management components that easily
131 integrate with business processes. Additional capabilities, for example policy-based management
132 and optimization, are composable into management systems enabling new levels of business
133 adaptivity. WSDM allows management components to become a direct part of a business
134 process. The systems management community can use the same business process technology
135 to develop automated management processes. Integration at this level enables every business to
136 adapt and respond to changing market environments in a more competitive, cost effective and
137 timely manner. Thus, a strategy of utilizing broadly adopted, industrial strength tooling and

138 runtime technologies will yield a better, more seamless integration among systems management
139 processes, solutions and business applications.

140 **2.2 A Day in the Life of a WSDM-Enabled Resource**

141 To understand a concept, it is often said that one must walk in another's shoes. To this end, this
142 section presents the concept of a day in the life of a resource with WSDM and without it.

143 The initial vision of WSDM was to standardize the way IT environments interoperate. However,
144 the vision of WSDM as a management framework is widening to a vaster array of possibilities
145 beyond the original intent of WSDM. WSDM seeks to specify that anything within a web services
146 framework could be WSDM management-enabled. That is, being able to collect and manage
147 information from IT resources such as printers and PDAs. In addition, managing consumer
148 electronic devices such as DVD players, televisions, and car radios is more than a possibility.
149 With the rapid adoption of service oriented architectures by commercial vendors, systems
150 integrators and industry standards organizations, the need for management standardization is
151 great.

152 **2.2.1 Consumer Electronics Manufacturer**

153 For one example, take a typical problem faced daily by a large manufacturer of projection
154 televisions-technical support. It is often easy to diagnose problems over the phone between a
155 technician and the consumer. However, in those times when catastrophic failure of the television
156 has created a condition that makes the problem indistinguishable for a consumer or technician,
157 WSDM can alleviate some of the problems that this kind of situation creates.

158 Projection televisions are large and cumbersome and it may not be profitable or even realistic for
159 a consumer to ship it back to the manufacturer. The current solution for most manufacturers is to
160 have on-site repair by factory-trained and certified technicians. The cost to maintain and train
161 these technicians is high and presents a huge overhead cost that not all manufacturers are willing
162 to pay. So how can WSDM help in this situation?

163 WSDM does not create a web services client, server or service oriented architecture. WSDM
164 simply provides the management framework upon which to build management applications. In
165 the case of the projection television manufacturer, the manufacturer could service-enable and
166 "WSDM-enable" its projection televisions before they are shipped from the manufacturing plant.
167 The television manufacturer could then create management based applications that proactively
168 diagnose problems instead of doing diagnosis in a reactionary mode.

169 For example, most projection televisions use lamps that eventually fail and have to be replaced
170 by the consumer. It would be extremely cost beneficial as well as reputation-building to both the
171 consumer and manufacturer to have the television "WSDM-enabled" to proactively diagnose the
172 potential of failure of the consumer's television lamp and automatically ship the consumer a new
173 lamp before it fails. In this respect, "WSDM-enabling" a device makes perfect sense.

174 **2.2.2 Managing the Network**

175 In another example of the potential application of WSDM, the arena of network management is
176 high on the agenda of most organizations that manage IT infrastructures. Not all devices in the
177 network management sphere have compatible protocols or even run the same application to
178 manage their devices on the network. These include routers, load balancers, security gateways

179 as well as managed switches. What WSDM provides is a standard by which any of these devices
180 can access management operations. It provides also a discovery as well as notification
181 mechanism for these devices to automatically discover each other to share management related
182 operations and data.

183 **2.2.3 Managing Printers by the Local Systems Administrator**

184 Most Systems Administrators are taxed with the burden of knowing multiple management
185 applications, hardware and network applications; generally at the expense of on-the-job training
186 by the employer. This does nothing but to cause frustration and management headaches to the
187 Systems Administrator. In an ideal world, all devices would have the same protocol, same network
188 architecture, and produce the same results. However, all devices in the real world sometimes
189 become single points of consternation because they only solve one issue needed by the
190 consumer.

191 Printers are one example of this. Printers cannot manage themselves but they can be managed.
192 They talk multiple languages to their printers such as PCL, PostScript, HPGL, and PCL-V. They
193 all have management applications that enable either simple or complex management tasks such
194 as alignment and print quality. However, every manufacturer's management application
195 framework is different.

196 However, WSDM can give printers a framework to be single application management-enabled;
197 either remotely or within a local network. This can enable the Systems Administrator to deploy
198 profiles for printers and simply plug the printer into a network, instantly have it available to all
199 users in the network and have it instantly discoverable to the management application of their
200 choice. Manufacturers can benefit from WSDM-enabling devices by providing metrics on data
201 sent to the printer. This could allow manufacturers to design printers for the way and manner
202 they are used; based upon usage patterns, real-time and historical configurations and types of
203 data being sent to printers.

204 **2.2.4 Managing Web Services**

205 Using WSDM, management applications can actually use web services to manage the very
206 service oriented architectures upon which they're built. This is an actual standards extension of
207 WSDM as a management framework also known as Management of Web Services (MOWS).
208 This is discussed in detail in section 5.2, "Organization of the WSDM Standard".

209 Imagine a management framework that enables other web services to proactively diagnose and
210 fix problems before they occur. This kind of scenario is especially important in service oriented
211 architectures. Because there is not a single point of failure for this type of architecture, web
212 services could fail without notifying other web services or devices on the network. So for a web
213 service to proactively choose a web service based upon quality of service, latency, or actual jitter
214 of the network transport makes a strong case for proactive management. WSDM enables web
215 services to proactively manage each other; thereby decreasing the potential of failures in service
216 oriented architectures and increasing the confidence of the actual consumers of web services.

217 **3 The Objectives of WSDM**

218 **3.1 Architectural Origins of WSDM**

219 WSDM was developed with a set of architectural foundations as its base; namely Web Services
220 **[WS-Arch]** and Service Oriented (SOA) Architectures. WSDM itself is a specification and
221 specification set, MUWS and MOWS, for managing devices as well as web services using web
222 services; which are inherently dependent upon a Service Oriented Architecture foundation. The
223 objectives of the specifications are many fold and these are described in the following sub-
224 sections.

225 **3.1.1 Resource Orientation**

226 Historically, managers have accessed resources through management agents running on the
227 resource. Some management agents support standard protocols for communication, like SNMP
228 and WBEM, some are proprietary. In addition, the way that the agents communicate with the
229 resource can be standard or proprietary. Managers accessing these resources would have to find
230 the resource, find which agent was responsible for the resource, ask the agent for information
231 about the resource or to make changes to the resource. This created a situation for managers
232 where layers of discovery were being done as well as support for an ever growing number of
233 protocols to agents. Besides resource access, many agents also provide many other useful
234 services for managers.

235 By describing and offering resource access interfaces for RESOURCES directly rather than
236 through intermediaries, WSDM makes resources Web services which can now participate directly
237 in a service oriented architecture and business processes. It also allows the managers to
238 concentrate on what resource they need to affect rather than having to keep track of which
239 agents control, resources and protocol switching. The Web services infrastructure and bridges to
240 agents take care of addressing and accessing the resource. This does not imply that agents are
241 no longer part of the management infrastructure; agents are still providers of key management
242 services and, as described in the next section, are excellent places to implement bridges to
243 WSDM to provide integration for its resources into the WSDM SOA.

244 **3.1.2 Implementation Isolation**

245 Because WSDM is based on Web services, one is able to use the loose coupling features,
246 platform agnosticism, and service orientation enabled by Web services to isolate manageable
247 resources access from their manageable resource implementations. The clients' use of a
248 manageable resource is consistent regardless of what implementation choices have been made.
249 In fact, a resource's implementation can migrate over time from a bridge to provide immediate
250 support to direct support by the resource without impacting management application and others
251 who may be using the manageable resource. It can even migrate from Java to C implementation
252 during this transition with no effect on the clients. Some common implementation topologies will
253 be:

- 254 • Bridges to Agents to access all resources as WSDM manageable resources

- 255
- 256
- 257
- 258
- Proxies or adapters for the manageable resource which communicates in another protocol or native API to the resource. Proxies may be collocated with the resource or not. This allows existing resources to participate in WSDM without affecting their instrumentation.
- 259
- Direct support by a resource can be provided when the resource is capable of running a Web services stack or receiving, parsing, and responding to SOAP messages **[SOAP]**. Web services stacks can be surprisingly small; some are less than 40k bytes.
- 260
- 261

262 **3.1.3 Composability of Services**

263 WSDM needs to scale in several directions: small, constrained devices to large, sophisticated
264 systems, as well as a few resources to hundreds of thousands of resources. In order to scale, the
265 specification takes advantage of the composability of services afforded by Web services
266 architectures. WSDM requires very few properties or operations; this means that the overhead of
267 supporting WSDM is very low for small systems. However, WSDM provides a rich set of
268 capabilities which can be used to provide descriptions of very sophisticated systems. This same
269 composability allows implementers and deployers to compose in support for appropriate levels of
270 qualities of service, like security, reliable messaging, brokered notifications, XPath **[XPath]**
271 support, etc. This is a key feature of Web services and WSDM.

272 **3.1.4 Model Agnostic**

273 WSDM describes HOW to access management data pertaining to managed resources by means
274 of a Web service protocol. This protocol makes use of management related concepts. These
275 concepts serve to structure the management data into categories that would be useful to a
276 management system. These categories, called manageability capabilities in WSDM, help to
277 define a protocol that is uniquely useful to management applications.

278 On the other hand, WSDM itself does not define a data or information model. That is, it does not
279 define the properties, operations, relationships, and events of managed resources. WSDM can be
280 used to provide Web services interfaces for resources described by any resource generic model,
281 such as CIM, SID, SNMP, or proprietary models. This feature is what we call model agnosticism.
282 A goal of WSDM was to provide protocol specifically designed for management and imbedding
283 management concepts while preserving independence of any particular model, including CIM,
284 SID, or SNMP, of managed resources themselves. Thus, legacy application can be easily
285 wrapped with a WSDM interface to provide Web services access to the model already used by
286 the application.

287 **3.1.5 Enabling Inspection**

288 WSDM enables inspection (or discovery) of resource interfaces (properties, operations and
289 events) at design time where there is no resource to ask directly, as well as at run time where
290 finding and processing XML documents **[XML]** may be expensive. It is important that the
291 managers are able to determine and integrate resource types and expected resources to manage
292 without imposing that the resource already be installed and running. This is especially important
293 where those resources are in the process of being installed, provisioned, and activated.
294 Therefore, it's also necessary for managers to 'discover' new instances of resources in their
295 environment and to attempt to understand and accommodate them as much as possible. For this
296 reason, it's important that manageable resources not only support the Web services messages,

297 it's also important that there are WSDL **[WSDL]** and XML schemas **[XML Schema]** to describe
298 them that are accessible at design and run time.

299

4 What is WSDM?

300 The WSDM standard specifies how the manageability of a resource is made available to
301 manageability consumers via Web services. This section describes the principal components of
302 the WSDM architecture, its modes of interaction used and the facilities it provides in support of
303 this architecture and interaction.

304 The focus of the WSDM architecture is the **manageable resource**. The manageable resource
305 must be represented as a Web service. In other words, management information regarding the
306 resource must be accessible through a **Web service endpoint**. To provide access to a resource,
307 this endpoint must be able to be referenced by an endpoint-reference, or **EPR**, as defined in the
308 WS-Addressing [**WS-Addressing**] standard. Endpoints that support access to manageable
309 resources are called manageability endpoints. The implementation behind manageability
310 endpoints must be capable of retrieving and manipulating the information related to a
311 manageable resource.

312 The EPR provides the target location to which a **manageability consumer** directs messages.
313 The manageable resource may also direct notifications of significant events to a manageability
314 consumer, provided the consumer has subscribed to receive notifications. Thus, WSDM covers
315 three modes of interaction between a manageable resource and a manageability consumer.
316 These modes of interaction are as follows:

- 317 • A manageability consumer can retrieve management information about the manageable
318 resource. For example, the consumer can retrieve the current operating status of the
319 manageable resource or the current state of the process running on the manageable
320 resource.
- 321 • A manageability consumer may affect the state of some manageable resource by
322 changing its management information.
- 323 • A manageable resource may inform, or notify, a manageability consumer of a significant
324 event. This mode of interaction requires the manageability consumer to subscribe to
325 receive events on a desired topic.

326 WSDM is about defining a common manageability structure and message exchange format
327 through which a manageable resource and a manageability consumer can *talk* to each other
328 regardless of implementation or platform. Compliance with the WSDM standard requires that both
329 manageable resource and manageability consumer are able to generate messages of the
330 specified format and are able to accomplish certain resource management goals. Thus, WSDM
331 defines a Web service message protocol for management information that may be shared by
332 manageable resource and manageability consumer in a vendor-neutral, platform-independent
333 manner.

334 A WSDM service is a management interface for a manageable resource present on the Web.
335 However, WSDM, with some minor exceptions such as WSDM metrics, does not itself specify the
336 content of any accessible management information. Only the format for retrieving and for
337 manipulating management information is specified by the WSDM standard.

338 In summary, this section highlights the three components of the WSDM architecture, the
339 manageable resource, the Endpoint Reference (EPR), and the manageability consumer and the
340 three modes of interaction between these components.

341 The following sections describe the facilities used by WSDM to support this interaction among
342 components. These facilities are the building blocks of the WSDM architecture.

343 **4.1 The Resource Property Document**

344 The XML representation of a manageable resource is described by an XML document called the
345 **resource properties document**. This document is referenced from a WSDL port type describing
346 the operations of the Web service representing a manageable resource. For further information
347 regarding the resource property document, see section 5.1, "The WSDM Technology Stack", in
348 this introduction.

349 A resource property exposes some information that is part of the state model for a manageable
350 resource. The resource property document represents a logical composition of resource property
351 elements presenting a view of the state of a manageable resource. The resource property
352 document plays the central role in exposing the state of a manageable resource.. Construction of
353 XML Schemas that describe the structure of resource property documents is covered extensively
354 in the WSDM Primer.

355 **4.2 Manageability Capabilities**

356 A manageability capability is a set of properties, operations, and events, enabling a resource to
357 be managed in a particular way. A manageable resource must be capable of supporting one or
358 more capabilities that expose the manageable features of the resource. The manageability
359 capabilities of a resource are part of the metadata describing the resource. Manageability
360 capabilities are described in a resource property document associated with a manageable
361 resource. Each capability is associated with a (possibly empty) set of properties, operations and
362 events supported by a manageable resource and exposed via a Web service interface.

363 The WSDM-defined manageability capabilities and their supported facilities are as follow:

364 The **Identity** capability exposes the ResourceId of a manageable resource. A ResourceId is a
365 globally unique identifier that is neither mutable nor modifiable. The ResourceId is correlatable: if
366 two reported ResourceIds are identical, then they refer to the same manageable resource.

367 The **ManageabilityCharacteristics** capability exposes a list of ManageabilityCapability elements.
368 Each element in the list denotes a capability supported by the manageable resource. Each list
369 element is either a WSDM specified manageability capability or a capability that is specific to the
370 type of manageable resource.

371 The **CorrelatableProperties** capability exposes a list of properties whose values are useful when
372 determining whether two different ResourceIds from two different manageability providers actually
373 refer to the same manageable resource.

374 The **Description** capability exposes the Caption, Description, and Version properties of the
375 manageable resource.

376 The **State** capability exposes the current state and the last state transition of a manageable
377 resource. The WSDM specification allows a resource to define its own state model. Support for
378 this capability indicates that information about the state model of a manageable resource can be
379 retrieved by a manageability consumer. For example, a resource may expose information about
380 its current state and last state transition.

381 The **OperationalStatus** capability exposes the high-level health of a manageable resource from
382 a simple operational perspective. The OperationalStatus property of a resource may have one of
383 the following values: Available, PartiallyAvailable, Unavailable or Unknown.

384 The **Metrics** capability exposes metric information relevant to the performance and operation of a
385 manageable resource. WSDM defines some metrics for a Web service resource and allows all
386 resources to define any suitable and relevant metrics.

387 The **Configuration** capability exposes properties of the manageable resource that can be
388 modified by the manageability consumer and which change the operation behavior of the
389 resource.

390 The following list of capabilities is related to the management of a manageable resource.
391 However, these capabilities may also be offered by endpoints other than manageability
392 endpoints. For example, a registry endpoint may offer one or more of the following capabilities:

393 The **Relationships** capability exposes the relationships in which a resource participates.
394 Facilities exposed by this capability include retrieving relationships, querying a resource for its
395 participation in a specific type of relationship, and notifying on the creation or the deletion of a
396 relationship in which the resource participates

397 The **RelationshipResource** capability exposes the properties of a manageable resource
398 representing a relationship. These properties may include the name, type and role in the
399 relationship

400 The **Advertisement** capability exposes a mechanism that emits a notification upon the creation
401 or destruction of a manageable resource. See section 4.5, "Advertisement", for further discussion
402 of this capability

403 A URI is used to represent each manageability capability. These URIs are specified in the WSDM
404 specification and are considered opaque identifiers to the manageability consumer. A WSDM
405 service must implement a minimum set of these capabilities. For example, the Identity capability
406 must be implemented on every WSDM manageable resource. In addition to the WSDM defined
407 capabilities, oother resource-specific capabilities may also be implemented.

408 **4.3 Management Events**

409 Management events are asynchronous notifications denoting a significant change of state in a
410 manageable resource. In some cases the principal message exchange pattern between a
411 manageable resource and a manageability consumer will take place via notifications rather than
412 via the consumer requesting management information from the resource. Notifications and
413 management events allow a manageability consumer to efficiently monitor the state of a
414 manageable resource.

415 Each management capability (see section 4.2, "Manageability Capabilities") is associated with a
416 topic on which notifications can be generated. For example, the topic associated with the State
417 capability is StateCapability. WSDM defines additional topics for specific situations. Each topic in
418 WSDM is associated with a message type of ManagementEvent. In other words, a message
419 issued on a topic associated with a manageability capability has a precise format specified by the
420 WSDM Event Format (WEF). The WEF contains an eventId, information regarding the source of
421 the event, the reporter of the event, a message about what happened to the resource, and the
422 date and time of the event. Notification messages contain additional information unique to the

423 specific event; for example, a state transition event includes Time, TransitionIdentifier,
424 EnteredState, and PreviousState.

425 A manageability consumer subscribes to management events on the topics supported by the
426 resource. In a subscription, the manageability consumer specifies the target resource, the topic of
427 the desired event messages, any filtering that the service should provide when formatting the
428 message for the subscription, and the desired form of delivery. A manageability consumer can
429 later unsubscribe from the event topic.

430 **4.4 Message Exchange Patterns**

431 The WSDM specification defines a set of Message Exchange Patterns (MEPs) that support how a
432 manageable resource and a manageability consumer may interact. MEPs may involve requests
433 and responses exchanged between a manageability consumer and a manageable resource, for
434 example within SOAP messages. MEPs are based upon the operations supported by a
435 manageability interface. These supported operations are classified into three categories.

- 436 • Manageability consumer requests to the manageable resource for property information
- 437 • Manageability consumer commands to the manageable resource
- 438 • Manageability consumer subscriptions and manageable resource generated notifications.

439 **4.4.1 Requests for Property Information**

440 A request for property information relies upon a message exchange pattern (MEP) that draws
441 from a certain set of operations on a manageability endpoint. This set of operations is as follows:

- 442 • The **GetResourceProperty** operation retrieves the value of a specified resource property
443 for a manageable resource.
- 444 • The **GetMultipleResourceProperties** operation retrieves values for a specified set of
445 resource properties for a manageable resource
- 446 • The **QueryResourceProperties** operation retrieves a portion of the resource properties
447 document from a manageable resource using a query language such as XPath [**XPath**]
- 448 • The **QueryRelationshipsByType** operation retrieves information on a particular type of
449 relationship in which the resource participates. This operation is defined in the WSDM
450 specification

451 For examples of MEPs based upon these operations, see the appropriate WSDM specification or
452 the WSDM Primer. Except as otherwise noted, all operations are defined in the WS-
453 ResourceProperties specification upon which the WSDM specification is built. See section 5.1,
454 "The WSDM Technology Stack" for additional information about the WS-ResourceProperties
455 specification.

456 **4.4.2 Commands to the Resource**

457 A request to change the value of a resource property relies upon a message exchange pattern
458 (MEP) that draws from a certain set of operations on a manageability endpoint. This set of
459 operations is as follows:

- 460 • The **SetResourceProperties** operation takes resource properties as supplied by a
461 manageability consumer and correspondingly modifies (inserts, updates, and/or deletes)
462 the given properties in the resource property document for a manageable resource.

463 For examples of MEPs based upon these operations, see the appropriate WSDM specification or
464 the WSDM Primer. Except as otherwise noted, all operations are defined in the WS-
465 ResourceProperties specification upon which the WSDM specification is built. See section 5.1,
466 "The WSDM Technology Stack" for additional information about the WS-ResourceProperties
467 specification.

468 **4.4.3 Subscriptions and Notifications**

469 A request for a subscription relies upon a message exchange pattern (MEP) that draws from a
470 certain set of operations on a manageability endpoint. This set of operations is as follows:

- 471 • The **Subscribe** operation requests that notifications be sent to a manageability consumer
472 • The **GetCurrentMessage** operation requests that a notification producer for a
473 manageable resource return the last notification on a given topic
474 • The **PauseSubscription** operation requests a temporary hold on an existing subscription
475 for a manageability consumer. A paused subscription continues to exist but does not
476 propagate notifications during the period of time it is paused.
477 • The **ResumeSubscription** operation requests the re-activation of paused subscription
478 for a manageability consumer.

479 In addition, the manageability consumer of Notifications may support the following operation:

- 480 • The **Notify** operation receives notifications on behalf of a manageability consumer

481 The WS-Notification family of standards also supports the distribution of notifications through
482 intermediaries, such as messaging software. A NotificationBroker requires many of these
483 operations as part of its interface. For example, a NotificationBroker is required to support the
484 Subscribe and Notify operations. The WS-BrokeredNotification specification specifies MEPs that
485 rely upon a certain set of operations that must be supported by the NotificationBroker. This set of
486 operations is as follows:

- 487 • The **RegisterPublisher** operation creates the registration of a manageable resource as a
488 notification publisher at a NotificationBroker
489 • The **Destroy** operation destroys the registration of a manageable resource at a
490 NotificationBroker.

491 For examples of MEPs based upon these operations, see the appropriate WSDM specification or
492 the WSDM Primer. Except as otherwise noted, all operations are defined in the WS-
493 BaseNotification specification upon which the WSDM specification is built. See section 5.1, "The
494 WSDM Technology Stack" for additional information about the WS-ResourceProperties
495 specification.

496 **4.5 Advertisement**

497 The Advertisement capability constitutes a special type of notification. The Advertisement
498 capability is exposed by a Web service to provide a notification on the creation or the destruction

499 of a manageable resource. Note that a Web service may offer this capability even though the
500 Web service itself is not a manageable resource.

501 For example, a system might include a registry of resources. A registry entry is added as a
502 resource is created. The corresponding registry entry is removed as a resource is destroyed. This
503 registry of resources could then expose the creation and destruction information via the
504 Advertisement capability. Through the Advertisement capability our example system would
505 expose resource creation and destruction events with manageability consumers. A typical means
506 of collecting diverse manageable resources into a registry is to use a service group as defined in
507 the WS-ServiceGroup specification.

508 Notifications generated under the Advertisement capability are produced on the following topics:

- 509 • The creation of a manageability endpoint
- 510 • The creation of a manageable resource
- 511 • The destruction of a manageability endpoint
- 512 • The destruction of a manageable resource.

513 5 Structure of the WSDM Standard

514 The WSDM standard is built upon W3C and other OASIS standards. This section briefly
515 summarizes the WSDM technology stack. It also describes the organization of the WSDM
516 specification itself.

517 5.1 The WSDM Technology Stack

518 The eXtensible Markup Language (XML) is the fundamental technology underpinning the WSDM
519 technology stack. All WSDM messages are serialized and transported as XML documents. The
520 format of such a document is rigorously defined via XML Schema and respective standards.
521 WSDM also uses XML Schema to define critical portions of the message exchange between a
522 manageable resource and a manageability consumer.

523 The WSDM specification relies upon two fundamental Web services technologies, SOAP and
524 WSDL. Since a key component of the WSDM architecture is the Endpoint Reference (EPR), the
525 WSDM specification also relies upon the W3C WS-Addressing standard. SOAP messages
526 directed to a manageable resource must conform to the EPR-to-SOAP bindings as described in
527 the WS-Addressing standard.

528 WSDM uses WSDL to describe the interface provided by a manageability endpoint. The WSDM
529 Primer provides examples defining the construction of WSDL documents describing how a
530 manageability consumer can access the manageability capabilities of a manageable resource.

531 The next level of the WSDM technology stack consists of a set of OASIS standards specifying
532 how to represent and access an XML representation of a resource. This set of standards is
533 generally referred to as the WS-ResourceFramework. A WS-Resource is a Web service that
534 exposes an XML representation of a resource. An external-facing Web service providing the
535 manageability for a resource must be capable of providing information about the state of the
536 resource.

537 Note that a manageable resource is also a WS-Resource. However, a WS-Resource is not
538 necessarily a manageable resource. In other words, the WSDM standard extends the definition of
539 WS-Resource by composing manageability capabilities with a WS-Resource.

540 The WS-ResourceFramework set of standards consists of the following standards:

- 541 • The WS-Resource **[WS-Resource]** specification specifies the basic notion of a WS-
542 Resource. This specification should be read before beginning work with the WSDM
543 standard
- 544 • The WS-ResourceProperties **[WS-ResourceSpecification]** specification defines the
545 resource properties document. This specification should be read before beginning work
546 with the WSDM standard.
- 547 • The WS-ResourceLifetime **[WS-ResourceLifetime]** specification specifies the interface
548 for destroying a WS-Resource
- 549 • The WS-ServiceGroup **[WS-ServiceGroups]** specification defines how WS-Resources
550 may be grouped in a set

551 • The WS-BaseFaults [**WS-BaseFaults**] specification defines a standard format for fault
552 messages

553 The WS-ResourceProperties specification requires that every WS-Resource must be exposed
554 through a resource property document. This is the reason why the resource property document is
555 considered to be one of the fundamental building blocks of the WSDM standard. See section 4.1
556 "The Resource Property Document" for additional information about the resource property
557 document. The WS-ResourceProperties specification also defines the relationship between a
558 Web service endpoint and the resource property document for an underlying stateful resource. A
559 resource property document must be described in the WSDL using XML Schema (type definition).
560 The type of a resource property document is established by the root element of the XML Schema
561 and is associated with a WSDL portType exposing the operations of a WS-Resource. This
562 association is achieved via a WS-ResourceProperties defined attribute @ResourceProperties.

563 In the following example, *wsrf-rp* is the namespace prefix referring to the WS-ResourceProperties
564 specification, *MyPdaDeviceProperties* is the root element of the XML Schema and *pda-prop*
565 refers to the namespace defined by the XML schema. The following example describes a
566 resource property document for a device called *MyPdaDevice*:

```
567 <portType name="MyPdaDevicePortType"  
568 wsrf-rp:ResourceProperties="pda-prop:MyPdaDeviceProperties">
```

569 A WS-Resource must implement a logical resource property document of the type declared with
570 its WSDL portType.

571 A final set of OASIS specifications define the Message Exchange Patterns (MEPs) involved in
572 subscriptions and notifications. These standards provide the following:

573 The WS-Topics [**WS-Topics**] specification defines how topics, on which subscriptions and
574 notifications are based, are represented in XML. This specification should be read before
575 beginning work with the WSDM standard

576 The WS-BaseNotification [**WS-BaseNotification**] specification defines the basic structure of
577 subscription and notification messages. This standard should be read before beginning work with
578 the WSDM standard

579 The WS-BrokeredNotification [**WS-BrokeredNotification**] specification defines an advanced
580 architecture for subscriptions and notifications over Web services involving a third-party message
581 recipient/distributor

582 In particular, the WSDM standard specifies additional topics dealing with management events to
583 which manageability consumers may subscribe for a manageable resource. In addition, the
584 WSDM standard augments the structure of an event contained in a notification with special
585 features pertaining to the management of the event and of likely interest to a manageability
586 consumer.

587 **5.2 Organization of the WSDM Standard**

588 The WSDM standard consists of two standards known as Management Using Web Services
589 (MUWS) and Management of Web Services (MOWS).

590 The MUWS standard deals with the basic mechanisms and Message Exchange Patterns (MEPs)
591 for managing any manageable resource *using* Web services as the platform for exchanging

592 messages. MUWS defines the manageability capabilities described in section 4.2, "Manageability
593 Capabilities". MUWS itself is specified in two parts:

- 594 ▪ MUWS part 1 [**MUWS Part 1**] addresses the fundamental capabilities of a manageable
595 resource. These fundamental capabilities include resource identity, manageability
596 characteristics, and correlatable properties. For more information on these MUWS
597 capabilities, see section 5, "Capabilities" of the WSDM Primer. MUWS part 1 also
598 provides a discussion of the WSDM Event Format (WEF). The interested reader is
599 directed to MUWS part 1 for a detailed explanation of the MUWS architecture and
600 principal concepts comprising the WSDM standard.
- 601 ▪ MUWS part 2 [**MUWS Part 2**] addresses the set of WSDM manageability capabilities
602 described in section 4.2, "Manageability Capabilities", other than those covered in MUWS
603 part 1.

604 MUWS part 1 and MUWS part 2 each have an XML Schema and a WSDL definition. These
605 documents should be incorporated into the definition of a manageable resource in order to make
606 use of MUWS facilities.

607 The MOWS [**MOWS**] standard addresses the management of a Web service itself. The MOWS
608 standard may be viewed both as an application of the WSDM MUWS standard and as an
609 extension of the WSDM MUWS standard

610 In MOWS, a Web service is the manageable resource. Keep in mind that a Web service itself, as
611 well as each process comprising the service, has state expressed by a state model as defined by
612 Web Service Management: Service Lifecycle [**WSLC**]. Thus, a Web service can be a target of
613 manageability by Web services. In addition to using the manageability capabilities and features of
614 the MUWS standard, the MOWS standard introduces its own manageability capabilities and
615 extends several MUWS capabilities to accommodate the special requirements of managing a
616 Web service.

617

618 **6 Summary**

619 To summarize, WSDM is not a panacea for all things management-related; however it can
620 provide a solid, standards-based framework for managing computing resources across the IT
621 environment or consumer devices halfway across the world. WSDM builds upon standards rather
622 than redefining or re-inventing technologies that already have strong industry footings. While it is
623 ideal to show real world examples of how this technology can be implemented, over time the
624 industry will shake out incompatibilities and inconsistencies within the WSDM standard through
625 actual successive and quality-controlled implementations. For further information on WSDM,
626 please reference the WSDM Primer on the OASIS home page as well as the base reference
627 specifications upon which WSDM is built in section 7, "References". For further information,
628 please contact the WSDM Technical Committee members as described in the status section from
629 the cover page.

712 **Appendix A. Acknowledgments**

713 The following people made contributions to the WSDM MUWS Primer Version 1.0: Vaughn
714 Bullard, Fred Carter, Mark Ellison, Heather Kreger, Richard Landau, Bryan Murray, Mitsunori
715 Satomi, Thomas Studwell, Kirk Wilson, Zhili Zhang with special thanks to Vaughn Bullard, Bryan
716 Murray, Kirk Wilson, and Mark Ellison as editors.

717 The following individuals were members of the committee while the WSDM MUWS Version 1.1
718 specification was developed and approved by the technical committee: Guru Bhat, Jeff Bohren,
719 Vaughn Bullard, Winston Bumpus, Fred Carter, Michael Clements, David Cox, Zulah Eckert,
720 Mark Ellison, John Fuller, Tony Gullotta, Heather Kreger, Richard Landau, Frederico Maciel, Tom
721 Maguire, David Melgar, Bryan Murray, Richard Nikula, Mark Peel, Mitsunori Satomi, Thomas
722 Studwell, William Vambenepe, Zhili Zhang.

Appendix B. Revision History

Rev	Date	By Whom	What
CD	2006-02-24	Kirk Wilson	Title changes
Final wd	2006-01-27	Kirk Wilson	Prepare final wd for TC vote
wd v5	2006-01-27	Kirk Wilson	Add references and acknowledgements
Introduction v1	2005-09-06	Vaughn Bullard, Kirk Wilson, Bryan Murray	Extracted Chapter 1 from Primer; made stand alone as WSDM Primer: An introduction to WSDM. Added references to base specifications in Section 5 References. Added Real World Examples, new Overview and Summary.
wd-12	2005-08-30	Bryan Murray	Incorporate review of section 3, formatting changes throughout
wd-11	2005-08-26	Bryan Murray, Mark Ellison, Kirk Wilson, Heather Kreger	Modified sections as homework to people at the f2f, critical review of section 1, updates to Relationships
wd-10	2005-08-22	Bryan Murray	Changes from f2f
wd-09	2005-08-19	Bryan Murray, Kirk Wilson, Heather Kreger	Added content to many sections
wd-08	2005-07-20	Kirk Wilson	Sections 1, 3, 5
wd-07	2005-07-26	Bryan Murray	Updates from June 2005 f2f. Add Advertisement section.
wd-06	2005-06-29	Bryan Murray, Winston Bumpus, Kirk Wilson, Richard Landau	Formatting, FCAPS, section 4, introduction
wd-05	2005-05-04	Zhili Zhang	Add section 2.4 "Adding Property Access Operations". Modify WSDL document in Appendix A.

Rev	Date	By Whom	What
wd-04	2005-04-27	Bryan Murray	Changes discussed during April f2f. Added text to Description section.
wd-03	2005-02-28	Bryan Murray	Outline revised based on Jan 2005 face-to-face, some section 2 content added
wd-02	2005-01-17	Bryan Murray	Revised outline to incrementally add capabilities
wd-01	2004-09-30	Bryan Murray	Initial version

Appendix C. Notices

726 OASIS takes no position regarding the validity or scope of any intellectual property or other rights
727 that might be claimed to pertain to the implementation or use of the technology described in this
728 document or the extent to which any license under such rights might or might not be available;
729 neither does it represent that it has made any effort to identify any such rights. Information on
730 OASIS's procedures with respect to rights in OASIS specifications can be found at the OASIS
731 website. Copies of claims of rights made available for publication and any assurances of licenses
732 to be made available, or the result of an attempt made to obtain a general license or permission
733 for the use of such proprietary rights by implementers or users of this specification, can be
734 obtained from the OASIS Executive Director.

735 OASIS invites any interested party to bring to its attention any copyrights, patents or patent
736 applications, or other proprietary rights which may cover technology that may be required to
737 implement this specification. Please address the information to the OASIS Executive Director.
